

# Introduction to meta-analysis

Presented by Catrin Tudur Smith and Sarah Nevitt

Cochrane Colloquium 2018

Trusted evidence. Informed decisions. Better health.

# **Steps of a Cochrane Review**

- 1. define the question
- 2. plan eligibility criteria
- 3. plan methods
- 4. search for studies
- 5. apply eligibility criteria
- 6. collect data
- 7. assess studies for risk of bias
- 8. analyse and present results
- 9. interpret results and draw conclusions
- 10. improve and update review

# **Session outline**

- principles of meta-analysis
- steps in a meta-analysis
- presenting your results

Source: Jo McKenzie & Miranda Cumpston

# What is a meta-analysis?

- combines the results from two or more studies
- estimates an 'average' or 'common' effect
- optional part of a systematic review

Source: Julian Higgins

# Why perform a meta-analysis?

- quantify treatment effects and their uncertainty
- increase power
- increase precision
- explore differences between studies
- settle controversies from conflicting studies
- generate new hypotheses

Source: Julian Higgins

### When not to do a meta-analysis

#### mixing apples with oranges

- each included study must address same question
  - consider comparison and outcomes
  - requires your subjective judgement
- combining a broad mix of studies answers broad questions
- answer may be meaningless and genuine effects may be obscured if studies are too diverse

### When not to do a meta-analysis

#### garbage in – garbage out

- a meta-analysis is only as good as the studies in it
- if included studies are biased:
  - meta-analysis result will also be incorrect
  - will give more credibility and narrower confidence interval
- if serious reporting biases present:
  - unrepresentative set of studies may give misleading result

Source: Julian Higgins

# When can you do a meta-analysis?

- more than one study has measured an effect
- the studies are sufficiently similar to produce a meaningful and useful result
- the outcome has been measured in similar ways
- data are available in a format we can use

# **Session outline**

- principles of meta-analysis
- steps in a meta-analysis
- presenting your results

# **Steps in a meta-analysis**

- identify comparisons to be made
- identify outcomes to be reported and statistics to be used
- collect data from each relevant study
- combine the results to obtain the summary of effect
- explore differences between the studies
- interpret the results

# **Selecting comparisons**

#### Hypothetical review: Caffeine for daytime drowsiness

caffeinated coffee

VS

decaffeinated coffee

- break your topic down into pair-wise comparisons
- each review may have one or many
- use your judgement to decide what to group together, and what should be a separate comparison

# **Selecting outcomes & effect measures**

Hypothetical review: Caffeine for daytime drowsiness

caffeinated coffee

vs de

decaffeinated coffee

- asleep at end of trial (RR)
- irritability (MD/SMD)
- headaches (RR)
- for each comparison, select outcomes
- for each outcome, select an effect measure
  - may depend on the available data from included studies

# **Common types of outcome data**

(1) Binary (or dichotomous) e.g. Survival status (Alive, Dead)

 For revman: Enter number of participants with events and total number of participants in experimental and control groups.

(2) Continuous e.g. blood pressure measurement

- For revman: Enter mean, standard deviation and number of participants in experimental and control groups

# **Types of effect measure**

(1) Binary (or dichotomous) data

Risk Ratio (or Relative Risk)

Odds Ratio

**Risk Difference** 

RR and OR are ratio measures - the 'null' value is 1

(2) Continuous data:

Mean Difference

**Standardised Mean Difference** 

RD, MD and SMD are difference measures – the 'null' value is 0

# **Calculating the summary result**

- collect a summary statistic from each contributing study
- how do we bring them together?
  - treat as one big study add intervention & control data?
    - breaks randomisation, will give the wrong answer
  - simple average?
    - weights all studies equally some studies closer to the truth
  - weighted average

# **Weighting studies**

- more weight to the studies which give more information
  - more participants, more events, narrower confidence interval
  - calculated using the effect estimate and its variance
- inverse-variance method:

weight = 
$$\frac{1}{\text{variance of estimate}} = \frac{1}{SE^2}$$
  
pooled estimate =  $\frac{\text{sum of (estimate \times weight)}}{\text{sum of weights}}$ 

### **For example**

Headache	Caffeine	Decaf	Weight
Amore-Coffea 2000	2/31	10/34	
Deliciozza 2004	10/40	9/40	
Mama-Kaffa 1999	12/53	9/61	
Morrocona 1998	3/15	1/17	
Norscafe 1998	19/68	9/64	
Oohlahlazza 1998	4/35	2/37	
Piazza-Allerta 2003	8/35	6/37	

### **For example**

Headache	Caffeine	Decaf	Weight
Amore-Coffea 2000	2/31	10/34	6.6%
Deliciozza 2004	10/40	9/40	21.9%
Mama-Kaffa 1999	12/53	9/61	22.2%
Morrocona 1998	3/15	1/17	2.9%
Norscafe 1998	19/68	9/64	26.4%
Oohlahlazza 1998	4/35	2/37	5.1%
Piazza-Allerta 2003	8/35	6/37	14.9%

# **Meta-analysis options**

- for dichotomous or continuous data
  - inverse-variance
    - straightforward, general method
- for dichotomous data only
  - Mantel-Haenszel (default)
    - good with few events common in Cochrane reviews
    - weighting system depends on effect measure
  - Peto
    - for odds ratios only
    - good with few events and small effect sizes (OR close to 1)

### **Meta-analysis options**

💐 New Outcome Wizard	
New Outcome Wizard Which analysis method do you want to use?	?
Statistical Method	Analysis Model
○ Peto	<u>Fixed effect</u>
<u>M</u> antel-Haenszel	○ <u>R</u> andom effects
⊖ Inverse Variance	
○ <u>E</u> xp[(O-E) / Var]	
Effect Measure	
⊖ Peto Odds Ratio	○ Mea <u>n</u> Difference
○ Odds R <u>a</u> tio	○ Std. Mean Difference
Risk Ratio	○ Name of Effect Measure:
○ Risk <u>D</u> ifference	Hazard Ratio
<u>C</u> ancel < <u>B</u> ack	<u>N</u> ext > <u>Finish</u>

# **Session outline**

- principles of meta-analysis
- steps in a meta-analysis
- presenting your results

• Heterogeneity

# Interpreting confidence intervals

- always present estimate with a confidence interval
- precision
  - point estimate is the best guess of the effect
  - CI expresses uncertainty range of values we can be reasonably sure includes the true effect
- significance
  - if the CI includes the null value
    - rarely means evidence of no effect
    - effect cannot be confirmed or refuted by the available evidence
  - consider what level of change is clinically important

(from Berry G. (1986), Med. J. Aust, 144: 618-619)

# **Presenting data in your review**

- present outcomes in consistent order throughout
  - Abstract, Methods, Results, data
- forest plots
  - key forest plots linked as figures
    - usually primary outcomes
  - all forest plots will be published as supplementary data
  - avoid forest plots with only one study
- may also add other data tables
  - results of single studies
    - summary data for each group, effect estimates, confidence intervals
  - non-standard data

# What to include in the protocol

- how will you decide whether a meta-analysis is appropriate?
- meta-analysis model to be used

# Take home message

- there are several advantages to performing a metaanalysis but it is not always possible (or appropriate)
- plan your analysis carefully, including comparisons, outcomes and meta-analysis methods
- forest plots display the results of meta-analyses graphically
- interpret your results with caution
